 XX
 CC This sequence represents a target alpha-helix sequence for the
 CC biarsenical compounds (BC) of the invention, which are able to react
 CC specifically with cysteine residues in a target sequence to generate a
 CC detectable signal. The BCs are used: (i) as labels that allow
 CC identification of carrier molecules, e.g. in polypeptide purification,
 CC immunoassays or other chemical or biological assays, including labelling
 CC in vivo, e.g. to identify, locate or quantify polypeptides or nucleic
 CC acids); (ii) for attaching a polypeptide to a solid substrate; or (iii)
 CC to induce a polypeptide domain to adopt a more nearly alpha-helical form,
 CC e.g. a conformation that can bind a drug. Tetra-arsenical compounds
 CC derived from the BCs are used to crosslink two binding partners, e.g. to
 CC study the effect of dimerisation on signal transduction. The BCs react
 CC specifically with Cys-containing targets, and can be engineered to have
 CC particular properties, especially ability to cross a biological membrane
 CC and absence of any self-fluorescence. Both the BC and its target sequence
 CC are small, and BC binding between them is reversible, e.g. by treatment
 CC with a dithiol. Particularly, the BC becomes fluorescent when bound to
 CC its target, but with a significant red-shift from the fluorescence of
 CC fluorescein, allowing detection with very low background

 XX
 CC This sequence represents a target alpha-helix sequence for the
 CC biarsenical compounds (BC) of the invention, which are able to react
 CC specifically with cysteine residues in a target sequence to generate a
 CC detectable signal. The BCs are used: (i) as labels that allow
 CC identification of carrier molecules, e.g. in polypeptide purification,
 CC immunoassays or other chemical or biological assays, including labelling
 CC in vivo, e.g. to identify, locate or quantify polypeptides or nucleic
 CC acids); (ii) for attaching a polypeptide to a solid substrate; or (iii)
 CC to induce a polypeptide domain to adopt a more nearly alpha-helical form,
 CC e.g. a conformation that can bind a drug. Tetra-arsenical compounds
 CC derived from the BCs are used to crosslink two binding partners, e.g. to
 CC study the effect of dimerisation on signal transduction. The BCs react
 CC specifically with Cys-containing targets, and can be engineered to have
 CC particular properties, especially ability to cross a biological membrane
 CC and absence of any self-fluorescence. Both the BC and its target sequence
 CC are small, and BC binding between them is reversible, e.g. by treatment
 CC with a dithiol. Particularly, the BC becomes fluorescent when bound to
 CC its target, but with a significant red-shift from the fluorescence of
 CC fluorescein, allowing detection with very low background
